Abundant and rare spiders on tree trunks in German forests (Arachnida, Araneae)

Theo Blick

Abstract: The spider fauna active on the bark of trees in forests on eight sites in different regions in Germany was investigated. Trunk eclectors at about 2-4 meters height on living trees were used in different regions of Germany (SW Bavaria, Hesse, Brandenburg) between 1990 and 2003. In Hesse eclectors were also used on dead beech trees (standing and lying). In this study data, mainly from beech (Fagus sylvatica) and spruce (Picea abies), from May to October are compared – whole year samples (including winter) are only available from Hesse. A total of 334 spider species were recorded with these bark traps, i.e. about one third of the spider species known from Germany. On average, each of the eight regions yielded 140.5 (± 26.2) species, each single tree 40.5 (± 12.2) species and 502 (± 452) adult spiders per season (i.e. May to Oct.). The 20 most abundant species are listed and characterised in detail. Six of the 20 species were not known to be abundant on bark, three prefer conifers and three beech/broadleaf. Even in winter (December-March) there was a remarkably high activity on the trunks. However, only a few species occur exclusively or mainly in winter. Finally, the rarity of some bark spider species is discussed and details (all known records in Germany, phenology) of four of them are presented (Clubiona leucaspis, Gongylidiellum edentatum, Kratochviliella bicapitata, Oreonetides quadridentatus). The diversity and importance of the spider fauna on bark in Central Europe is still underestimated.

Key words: bark, common species, distribution, eclectors, Germany, rare species

The spider fauna of tree trunks in Germany and Central Europe is much less well known than the epigeal fauna active on the forest floor. Only the fauna of the tree crowns is more poorly known (SIMON 1995, GOSSNER 2004, RÖDER et al. 2010). Furthermore, the epigeal spider fauna of common forest types – at least in Central Europe – is significantly less intensively investigated than that of the epigeal fauna of special habitats, such as those that are extremely dry or wet (HÄNGGI et al. 1995). I estimate that this disproportion is much higher, if one compares the epigeal spider fauna in forests with the tree trunk spider fauna. In Central European forests knowledge about the tree trunk fauna reaches an estimated maximum level of 5% compared with the epigeal fauna.

Before the research in Strict Forest Reserves in Hesse started, estimates of the species richness of animals (biodiversity) in a beech forest were 1500-2000 species (all animals) (ELLENBERG et al. 1986). Now we know that there are closer to 5000-6000 (DOROW et al. 2004, 2010). In each of the four Strict Forest Reserves investigated until now 162 to 202 spider species were recorded (BLICK 2009).

As the complete spider coenoses and species lists were already published (see below) or will be published elsewhere, the focus here is on the following topics: (a) totals of species and abundances, (b) the 20 most abundant spider species, (c) winter activity, and (d) notes on rarely or very rarely recorded species.

Methods

Trunk eclectors (Fig. 1, method after BEHRE 1989, see also BRAUN 1992, DOROW et al. 1992, ENGEL 1999) at heights from 2 to 4 meters on living trees were used in different regions of Germany (SW Bavaria, Hesse, Brandenburg) (Fig. 2). In Strict Forest Reserves in Hesse eclectors were also used on dead beech trees (standing trees and with an adapted type of trap, also on lying trees) (DOROW et al. 1992).

The traps were operated during different time periods in the different regions and projects. The trapping periods from May to October were available for comparison from nearly all sites (except Brandenburg). Hesse (Strict Forest Reserves) was the only area where data were available for the whole year, i.e. two entire years including two winters.

Most data sets are from beech – Fagus sylvatica and spruce – Picea abies; see details below.
Sites
The data included in this study came from different sites in Germany (Fig. 2):
• Three pairs of pine forests, also part mixed with beech and oak, in Brandenburg (no. 1 in Fig. 2, two forests in the north, one in the south) (unpubl. data from 2000 and 2001, June to September, leg. T. Taeger & U. Schulz, det. TB). In each of the six forests six trunk eclectors were installed on Scots pine – *Pinus sylvestris*. A total of 36 trees were investigated.

Figure 1: Trunk eclectors on standing beech trees in northern Hesse, Germany, a – spring, b – winter, c – dead tree
Spiders on tree trunks

- In four Strict Forest Reserves and their reference areas, where forestry is continued, in Hesse (nos. 2-5 in Fig. 2) trunk eclectors were installed on two living and two dead standing beech trees during two whole years (MALTEN 1999, 2001, MALTEN & BLICK 2007, BLICK 2009). Additionally at least two eclectors on lying dead beech trees were installed in each reserve. In total 30 standing and 13 lying dead trees were investigated.

- Mixed forest (‘Stadtwald’), between the urban area of Frankfurt am Main and its airport. 12 trees (alder – *Alnus glutinosa*, ash – *Fraxinus excelsior*, birch – *Betula pendula*, two beeches, douglas fir – *Pseudotsuga menziesii*, elm – *Ulmus laevis*, Scots pine, two common oaks – *Quercus robur*, sessile oak – *Quercus petraea*) were investigated with trunk eclectors in 2000 (beginning of February/mid-March to beginning of November) (MALTEN et al. 2003, det. in part by TB) (no. 6 in Fig. 2).

- Forest near Biburg, east of Augsburg, Bavaria (no. 7 in Fig. 2); eight young beeches, four young spruces (20-40 y), two older beeches, two older spruces (about 100 y); beginning of April to end of October 1996 (ENGEL 1999, 2001, det. mainly by TB).

- Forests near Krumbach and Ottobeuren, Bavaria (no. 8 in Fig. 2); 16 beeches, eight douglas firs, eight common oaks, two northern red oaks – *Quercus rubra*, two silver firs – *Abies alba*, 22 spruces (unpubl. data from 1999 to 2003, April to October, with exceptions of 1999 (beginning in June) and of 2000 (until November), leg. K. Engel & M. Gossner, det. TB).

Results

Totals

In total 334 spider species, i.e. one third of the spider fauna of Germany, were recorded with 98328 adult spiders. In the 8 different regions between 106 and 177 spider species were recorded, with an average of 140.5 species (± 26.2 standard deviation) (Tab. 1).

Figure 2: Sites with trunk eclectors in Germany, included into this study 1: forests in Brandenburg (Blick & Schultz unpubl.); 2-5: Strict Forest Reserves in Hesse (2: Hohestein, MALTEN & BLICK 2007; 3: Goldbachs- und Ziebachsrück, BLICK 2009; 4: Niddahänge östlich Rudingshain, MALTEN 1999; 5: Schönbusche, MALTEN 2001); 6: Stadtwald, Frankfurt am Main, Hesse (MALTEN et al. 2003); 7: forest near Biburg, east of Augsburg, Bavaria (ENGEL 1999, 2001); 8: forests near Krumbach and Ottobeuren, Bavaria (Blick et al. unpubl.); see text.
Between 21 and 88 spider species were recorded per tree and season (i.e. May–Oct. – based on 115 living trees/season and a total of 298 species), with an average (Ø) of 40.5 species (± 12.2). Altogether 122 to 2696 adult spiders per tree and season were trapped, Ø 502 (± 452).

**Twenty most abundant spider species**

In Tab. 2 the 20 most abundant spider species are sorted in descending abundance. Regional distribution (focus or exclusivity – if nothing is noted the species was recorded in every one of the 8 regions), the tendency to occur on broadleaves/conifers and other notes are added.

To summarise:
- 8 of the 20 species (40%) were linyphiids, 10 families were present
- only 2 species belong to the same genus (Xysticus)
- 6 species are not known yet as abundant bark species (compare e.g. WUNDERLICH 1982)
- 14 species are abundant in (nearly) all regions investigated, 6 species have a more regional distribution
- 3 species prefer conifers, 3 species prefer beeches/broadleaves [3 other species were only or mainly trapped in regions, where all/most of the traps were on beech/broadleaf]
- these 20 most abundant species make up 65281 adults, i.e. 66.4 % of the adult spiders from the trunks

**Most abundant spider species active in winter**

A similar analysis was made for the winter active species (trapping months December to March, including long winter trapping periods in the regions which ended at the end of April or even at the beginning of May in some years). This means that mainly data of the regions 2-5 (see Fig. 2) and only some additional data of region 6 could be analysed. All these data came from the federal state Hesse. A total of 140 species, 7356 adults and 15714 juveniles (9833 determinable to species level) were recorded during the winter periods.

Even in winter, numerous spiders were found in the trunk eclectors. Only two representatives of the commonly known winter-active spiders (e.g. the linyphiid genera Centromerus, Macrargus and Walckenaeria; the dictynid Cicurina) are on this list (Tab. 3). The majority of the species are also included in Tab. 2. Compared to the forest floor, fewer species on bark were exclusively active in winter. Only Cicurina cicur and Thyrosthenius parasiticus can strictly be placed in the latter category, but at some sites also Monochelus castaneipes. The 9 species with more than 100 adult individuals comprise 5930 (81%) of the adult spiders from the trunks in the winter – a much less balanced pattern than in the summer (see above).

**Rare spider species**

There are several ‘types’ of rare spider species: (a) widely distributed but rare, (b) at or near the border of their distribution area, (c) with restricted distribution areas (Central European endemics?). Examples of species for these types are listed as follows: species name (family), adults recorded (ind.), and distribution area. PLATNICK (2009), STAUDENT (2009) and MIKHAILOV (1997) were used as main sources for the total distribution of each species.

(a) widely distributed but rare

*Araneus saevus* (L. Koch, 1872) (Araneidae), 2 ind., Holarctic
*Carrhotus xanthogramma* (Latreille, 1819) (Salticidae), 59 ind., Palaeartic
*Dendryphantes hastatus* (Clerck, 1757) (Salticidae), 32 ind., Palaeartic
*Dipoena torva* (Thorell, 1875) (Theridiidae), 120 ind., Europe to W Siberia
*Mastigusa arietina* (Thorell, 1871) (Dictynidae), 3 ind., Europe
*Philodromus buchari* Kubcová, 2004 (= *P. longipalpis* auct. in Central Europe) (Philodromidae), 19 ind., Europe and Turkey
*Stroemiellus stroemi* (Thorell, 1870) (Araneidae), 1 ind., Palaeartic

Interestingly there are no records of the very rare tree-living species *Philodromus poecilus* (Thorell, 1872) (Philodromidae), Palaeartic (see MUSTER 2009) and *Xysticus albomaculatus* Kulczyński, 1891 (Thomisidae), Germany to Romania, probably Russia (see JANICHER 2001).

(b) at or near the border of their distribution

*Cinetata gradata* (Simon, 1881) (Linyphiidae), 76 ind., central and southern Europe, mainly in mountainous areas, its northern border of distribution is situated in Germany.
*Clubiona leucaspis* Simon, 1932 (Clubionidae) (Figs. 3a, 4a), 583 ind., southern and central Europe, i.e. the northern border is located in Germany, in Germany only in the north-eastern and south-western

Figure 3: Distribution maps for Germany of four of the rare spider species (after STAUDT 2009); a Clubiona leucaspis, 1 & 2: Blick & Schultz (unpubl.); 3 & 4: MALTEW et al. (2003); b Gongylidiellum edentatum, 1: BLICK (2009), 2: MALTEW (1999); c Kratochviliella bicapitata, 1-4: Blick et al. (unpubl.); d Oreonetides quadridentatus, 1: MALTEW (1999), 2: MALTEW (2001), 3: Blick et al. (unpubl.)
regions with the highest average temperatures, only lowlands. First record for Germany by MALTEN (1994). Note: some records of C. genevensis L. Koch, 1866 on trees might really represent further records of C. leucaspis. For the typical colouration see: http://spiderling.de/arages/Fotogalerie/spe-cies_fg.php?name=Clubiona%20leucaspi s

Gongylidiellum edentatum Miller, 1951 (Figs. 3b, 4b, 10 ind., central Europe (Germany, Czech Rep., Austria), N Italy, SE France, most numerous record (31 specimens) is from a rotting beech stump in Hesse (BLICK 2009), see also below.

Kratochviliella bicapitata Miller, 1938, 878 ind., central Europe (Germany, Austria, Czech Rep., Slovakia, Poland), Bulgaria; besides the specimens presented here there is just one other record of a larger number of individuals in Poland (CZAJKA & BEDNARZ 1972: “only on the northern surface of the tree trunks. ... We estimated that the whole population consisted of some 6000-7000 specimens at that time”), see also below.

Oreonetides quadridentatus (Wunderlich, 1972), 82 ind., central Europe (Germany, Austria, Luxembourg) and one record with four specimens from the French Pyrenees (BOSMANS et al. 1986); the

(c) with restricted distributions; central European ‘endemics’ (all belong to the Linyphiidae)
record presented here probably refers to the greatest number of individuals found until now. *Pseudocarorita thaleri* (Saaristo, 1971), 64 ind., central Europe (Germany, Czech Rep., Austria, Switzerland, Belgium).

More details on four of the rare species mentioned above are presented in Figs. 3 and 4, because very little information has previously been published on them. The phenologies of these four species are presented in Fig. 4. The trapping periods are assigned to the month to which the majority of the days of each trapping period belonged; this may not be the month in which the trap was changed or emptied. For *Gongylidiellum edentatum* and *Kratochviliella bicapitata* supplementary data are included, i.e. unpublished data from other sites, or from the sites mentioned in this paper but caught with methods other than trunk eclectors.

**Discussion**

TOFT (1976) caught 3195 spiders from the end of April to mid-December with ‘arboreal photoeclectors’ (method after NIELSEN 1974) but gave no species number for the individual methods used (total species number = 147). ALBERT (1982) was the first to publish detailed data from trunk eclectors (method after FUNKE 1971, i.e. without trapping bottles at the bottom; by contrast the type after BEHRE 1989 uses bottles at the bottom, Fig. 1). The eclectors were installed on beeches and spruces and were operated from March/April to November/December in 1969 and 1971. He gives no total species number for the trunk eclectors, but for the four investigated types: spruce old (52 species, 4025 adults), spruce young (39 sp., 972 ad.), beech old (67 sp., 1525 ad.), beech young (33 sp., 199 ad.). PLATEN (1985, also with the eclector type of FUNKE 1971) recorded 74 species over two whole years, 69 on beech and 37 on spruce.

Some other examples: BRAUN (1992), who already used the eclector type of BEHRE 1989, caught 108 spider species (3709 adults) on trunks of Scots pine at 3 different heights above the forest floor (1, 4 and 8 meters) from May to Oct. SIMON (1995), also trapped on Scots pine and at different heights (1.5, 5, 10 and 13 meters – species numbers 71, 59, 48, 35, i.e. lower numbers at increasing height), over 3 whole years collecting a total of 103 species (including traps on branches in the crown). GOERTZ (1998) examined 10 trees (5 crack willows – *Salix fragilis*, 2 almond willows – *Salix triandra*, 3 black poplars – *Populus aff. nigra*) from mid-December to end of June and caught a total of 100 species and 20167 determinable

![Figure 4: Phenology of (a) *Clubiona leucaspis*, (b) *Gongylidiellum edentatum*, (c) *Kratochviliella bicapitata*, (d) *Oreonetides quadridentatus* (black males, white females, grey juveniles; x-axis: Roman numerals represent the months; y-axis: numbers of trapped specimens); a *Clubiona leucaspis* (no traps operated from November/XI to January/II), totals 441 3 δ, 159 3 Φ, 1231 juv.; b *Gongylidiellum edentatum*, totals 12 δ, 45 Φ (incl. 3 δ, 7 Φ in long winter periods, i.e. Nov./Dec. to end of April/beginning of May – not included in this graph); c *Kratochviliella bicapitata*, totals 490 3 δ, 399 3 Φ; d *Oreonetides quadridentatus*, totals 4 3 δ, 83 Φ (incl. 1 δ in a longer winter period, i.e. mid Nov. to mid of March – not included in this graph)
Spiders on tree trunks

Acknowledgements
My thanks go: to Andreas Malten (Frankfurt am Main), who determined the spiders of three strict forest reserves and to Ingrid Weiss (Grafenau-Rosenau), who determined a part of the spiders from Frankfurt; to the whole team of the Strict Forest Reserve Project, especially to Wolfgang Dorow (Frankfurt am Main), the old stager of the project; to Aloisius Staudt (Schmelz) for his great work on the German www-distribution maps; to Tim Taeger and Ulrich Schultz (Eberswalde) for their field and lab work; to Kerstin Engel, Martin Goßner (formerly Freising), and Andreas Malten for collecting the spiders and for arranging finances; last but not least to Andrew Liston (Müncheberg) for improving the English. Research on the Strict Forest Reserves in Hesse was conducted in cooperation with and financially supported by the ‘Landesbetrieb Hessen-Forst’.
